

Useful answer? Show your working.

An AI tool can help you get started. You still need to decide what to trust, what to change and what to leave out.

15-20 minutes

Use with any factual answer

No personal data needed

Before you ask

- State the task, audience and format.
- Use fictional or public information.
- Remove names, identifiers and private details.
- Decide what a good answer must contain.

Before you use it

- Break the answer into separate claims.
- Check important claims outside the tool.
- Recalculate numbers and units.
- Describe uncertainty and acknowledge assistance where required.

The claim I am checking

Why does getting it right matter? What could go wrong?

Follow the evidence

CHECK	YOUR NOTES
Where is the original evidence? Author, organisation, title, link or page.	
Does the source actually support this claim? Read the relevant passage, not just the title.	
Is it current enough for this use? Date, location and relevant population.	
What independent check can I make? Calculation, original dataset or a suitable second source.	

Decision: ☐ supported for this use ☐ needs correction ☐ cannot verify

My corrected claim, with a source or calculation:

Privacy check: removing a name may not make a story anonymous. A combination of age, location, job or unusual events can still identify someone. Replace unnecessary details with fictional ones.

Check the claim. Keep the useful part.

The example below was invented for learning. It is not an output attributed to a particular AI service.

“At 5% annual inflation, a basket costing €80 today will cost €84 in two years. So you will need exactly €4 more.”

1 / Split it up

There is a stated starting price (€80), a rate (5% a year), a period (two years) and a conclusion (€84). The answer assumes the same basket and constant inflation, but uses only one year of price growth.

2 / Recalculate

After year 1: $€80 \times 1.05 = €84.00$

After year 2: $€84 \times 1.05 = €88.20$

The modelled two-year increase is **€8.20**, not €4. Saying “exactly” is also too strong for a forecast of real prices: the constant 5% rate is an assumption.

3 / Check the concept

The ECB’s inflation explainer describes broad price growth and its effect on purchasing power. It does not predict that this particular basket will rise by 5% every year. General inflation and your own spending pattern can differ.

4 / Write a better answer

“If this basket rises by 5% each year for two years, its modelled cost is $€80 \times 1.05^2 = €88.20$. That is €8.20 more than today. Actual prices can change differently; this is a fixed-rate example.”

Practice: choose what to share

POSSIBLE INPUT	SAFER CHOICE FOR THIS EXERCISE
A friend’s full bank statement	Do not upload it. Build a fictional table of rounded income and expense categories.
A classmate’s private health story	Do not share it. Ask a general question using an invented scenario if one is needed.
A public article you want summarised	Provide a link or an appropriate excerpt, state the task, and check the summary against the original.
A one-time sign-in code	Do not share it with an AI tool or someone who contacts you. Use it only in the intended sign-in flow you initiated.

Sources: [ECB: What is inflation?](#); [NIST: Generative AI Profile, section 2.2](#) (systems can confidently produce incorrect or invented content). A cited source must be opened and checked; citations can also be wrong.
